Abstract We have proposed an automatic speech summarization method through word extraction. In our proposed method, a set of words maximizing a summarization score consisting of word significance measure, linguistic likelihood, confidence measure and SDCFG (stochastic dependency context free grammar) is extracted from automatically transcribed speech. This extraction is performed using a Dynamic Programming (DP) technique according to a target compression ratio (summarization ratio) based on the number of words/characters in the original sentence. We have previously tested the performance of our method using Japanese speech such as broadcast news and lectures. Since our method is based on a statistical approach, it can be applied not only to Japanese but also other languages. In this paper, English broadcast news speech transcribed using a speech recognizer is automatically summarized. In order to apply our method to English, the model of estimating word concatenation probabilities based on a dependency structure in the original speech given by a Stochastic Dependency Context Free Grammar (SDCFG) is modified. In order to reduce the amount of computation, a summarization method for multiple utterances using two-level DP technique is conducted.

あらまし これまで、単語抽出による音声自動要約手法を提案してきた。本手法は、音声認識結果から、単語重要度、言語尤度、信頼尺度、係り受け SCFG に基づく要約スコアが最大となる部分単語列を抽出する。抽出される部分単語列は、原文の単語数または文字数に基づく特定の割合（要約率）で、動的計画法により決定する。これまで、日本語のニュースまたは講演の音声を対象として、提案手法により自動要約を行った。本手法は、確率モデルに基づく要約スコアを適用していることから、他言語への応用が可能である。本稿では、英語のニュースを音声認識し、自動要約した結果を報告する。英語の自動要約に適用するため、係り受け SCFG(Stochastic Context Free Grammar) に基づく単語間遷移確率を推定するモデルを、英語の係り受け構造を推定できるモデルに拡張した。また、複数の発話から構成された音声を要約する手法として、要約する文数の増加に伴い増加する計算量を削減するため、2 段 DP(Dynamic Programming) による複数発話自動要約手法を適用した。

キーワード 音声自動要約, 英語ニュース音声, 単語重要度, 言語尤度, 信頼尺度, 係り受け SCFG, 2 段 DP

1 Introduction

Currently various applications of LVCSR systems, such as automatic closed captioning [1], meeting/conference summarization [2] and indexing for information retrieval [3], are actively being investigated. Transcribed speech usually includes not only redundant information such as disfluencies, filled pauses, repetitions, repairs and word fragments, but also irrelevant information caused by recognition errors. Therefore, especially for spontaneous speech, practical applications using speech recognizer require a process of summarization which removes redundant and irrelevant information and extracts relatively important information depending on users' requirements. Speech summarization producing understandable sentences from original utterances can be considered as a kind of speech understanding.

We proposed an automatic speech summarization technique [4][6], and investigated its performance using Japanese broadcast news speech. Since our method is based on a statistical approach, it can be applied not only to Japanese but also other languages. In this paper, English broadcast news speech transcribed using a speech recognizer [7] is automatically summarized and evaluated. In order for our method to apply to English, a model to estimate dependency structures in original sentences based on Stochastic Dependency Context Free Grammar (SDCFG) is extended.

2 Summarization of Each Sentence Utterance

Our method to summarize speech, sentence by sentence, extracts a set of words maximizing a summarization score from an automatically transcribed sentence according to a summarization ratio. The summarization ratio is the number of characters/words in the summarized sentence divided by the number of characters/words in the original sentence. The summarization score indicating the appropriateness of a summarized sentence is defined as the sum of a word significance score I , a confidence score C of each word in the original sentence, a linguistic score L of the word string in the summarized sentence [4][5] and a word concatenation score T [6]. The word concatenation score given by SDCFG indicates a word concatenation probability determined by a dependency structure in the original sentence. This method is effective in reducing the number of words by removing redundant and irrelevant information without losing relatively important information. A set of words maximizing the total score is extracted using a DP technique [4].

Given a transcription result consisting of N words, $W = w_1, w_2, \dots, w_N$, the summarization is performed

by extracting a set of M ($M < N$) words, $V = v_1, v_2, \dots, v_M$, which maximizes the summarization score given by eq. (1).

$$S(V) = \sum_{m=1}^M \{L(v_m | \dots v_{m-1}) + \lambda_I I(v_m) + \lambda_C C(v_m) + \lambda_T T(v_{m-1}, v_m)\} \quad (1)$$

where λ_I , λ_C and λ_T are weighting factors for balancing among L , I , C and T .

2.1 Word significance score

The word significance score $I(v_m)$ indicates the relative significance of each word in the original sentence [4]. The amount of information based on the frequency of each word is used as the word significance score for topic words. We choose nouns and verbs as topic words for English. A flat score is given to words other than topic words. To reduce the repetition of words in the summarized sentence, a flat score is also given to each reappearing noun and verb.

2.2 Linguistic score

The linguistic score $L(v_m | \dots v_{m-1})$ indicates the appropriateness of the word strings in a summarized sentence and is measured by a N-gram probability $P(v_m | \dots v_{m-1})$ [4]. In contrast with the word significance score which focuses on topic words, the linguistic score is helpful to extract other words necessary to construct a readable sentence.

2.3 Confidence score

The confidence score $C(v_m)$ is incorporated to weight acoustically as well as linguistically reliable hypotheses [5]. Specifically, a posterior probability of each transcribed word, that is the ratio of a word hypothesis probability to that of all other hypotheses, is calculated using a word graph obtained by a decoder and used as the confidence measure [7].

2.4 Word concatenation score

The word concatenation score $T(v_{m-1}, v_m)$ is incorporated to give a penalty for a concatenation between words with no dependency in an original sentence. Suppose "the beautiful cherry blossoms bloom in spring" is summarized as "the beautiful spring". The latter phrase is grammatically correct but an incorrect summarization. The above linguistic score is not powerful enough to alleviate such a problem. In order to maintain original meanings, dependencies between words in the original sentences are necessary to be kept in summarized sentences. The word concatenation in a summarized sentence is restricted by the

3 Summarization of Multiple Utterances

The summarization method applied to each sentence can be extended to the summarization of articles consisting of multiple utterances as follows. Each utterance is summarized according to all possible summarization ratio and then the best combination of summarized sentences is determined according to a target compression ratio using a two-level DP technique [6]. Figure 4 illustrates the two-level DP technique for summarizing multiple utterances.

Figure 4: An example of DP process for summarization of multiple utterances.

4 Word Network of Manual Summarization Results for Evaluation

To automatically evaluate summarized sentences, correctly transcribed speech are manually summarized by human subjects and used as correct targets. The manual summarization results are merged into a word network which approximately expresses all possible correct summarization including subjective variations. A “summarization accuracy” of automatic summarization is calculated using the word network [6]. A word string that is the most similar to the automatic summarization result extracted from the word network is considered as a correct target for the automatic summarization. The accuracy, comparing the summarized sentence with the target word string, is used as a measure of linguistic correctness and maintenance of original meanings of the utterance.

5 Evaluation Experiments

5.1 Evaluation data

English TV broadcast news utterances (CNN news) recorded in 1996 given by NIST as a test set of Topic Detection and Tracking (TDT) were tagged by Brilltagger [10] and used to evaluate our proposed method.

Five news articles consisting of 25 utterances in average were transcribed by a speech recognition system. The multiple utterance summarization was performed for each of the five news articles at 40% and 70% summarization ratio. 50 utterances arbitrarily chosen from the five news articles were used for the sentence by sentence summarization with the summarization ratios of 40% and 70%. In order build a word network of manual summarization results, 17 native English speaker generated manual summarization by removing or extracting words.

5.2 Structure of Broadcast News Transcription System

English broadcast news speech was transcribed by the JRTk (Janus Speech Recognition Toolkit) [7] with the following conditions.

Feature extraction

Sounds were digitized with 16kHz sampling and 16bit quantization. Feature vectors had 13 elements consisting of MFCC. Vocal Tract Length Normalization (VTLN) and cluster based cepstral mean normalization were used to compensate for speaker and channel. Linear Discriminant Analysis (LDA) was applied to reduce feature dimensions in each segment consisting of 7 frames to 42.

Acoustic model

A pentphone model with 6000 distributions sharing 2000 codebooks were used. There were about 105k Gaussians in the system. The training data was comprised of 66 hours of Broadcast News(BN).

Language model

Bigram and trigram were built using BN corpus. Its vocabulary size was 40k.

Decoder

A word-graph-based 3-pass decoder which was composed with JRTk was used for transcription. In the first pass, frame-synchronous beam search was performed using a tree-based lexicon, the above-mentioned HMMs and a bigram model to generate a word graph. In the second pass, frame-synchronous beam search was performed again using a flat lexicon hypothesized in the word graph by the first pass and a trigram model. In the third pass, the word graph was minimized and rescored using the trigram language model.

5.3 Training data for summarization models

A word significance model, bigram and trigram language models and SDCFG were constructed using roughly 35M words (10681 sentences) of the Wall Street Journal corpus and the Brown corpus in Penn Treebank [9]. SDCFG was estimated using above-mentioned corpus without using nonterminal symbols. The number of nonterminals was set to 100.

The performance of the n-gram language models constructed using the newspaper text to represent the manual summarized sentences by human subjects was tested. Figure 5 shows the perplexity and out of vocabulary (OOV) rate compared between the bigram and trigram language models. Since the trigram, whose

Figure 5: *Perplexities and out of vocabulary rates of language models for summarization.* EACH: summarization sentence by sentence, MULTIPLE: summarization of multiple sentences, TRS: Manual transcription,

perplexity is higher than that of the bigram, is considered to restrict word strings too strongly in a summarized sentence, The bigram model was used for the linguistic score in this study.

5.4 Evaluation results

Manual transcription (TRS) and automatic transcription (REC) were both summarized. Mean word recognition accuracies of the utterances used for the multiple utterance summarization and those for sentence by sentence summarization were 78.4% and 81.4%, respectively. Table 1 shows examples of automatic summarization and the corresponding target extracted from a manual summarization word network. Figure 6 shows summarization accuracies of utterance summarization at 40% and 70% summarization ratio and Fig. 7 shows those of summarizing articles having multiple utterances at 40% and 70% summarization ratio. In these figures, *I*, *L*, *C* and *T* indicate that the word significance score, the linguistic score, the confidence score and the word concatenation score are used, respectively.

Figure 6: *Each utterance summarization at 40% and 70% summarization ratio.*

Figure 7: *Article summarization at 30% and 70% summarization ratio.*

In the summarization of REC, conditions with and without the word confidence score, (*I*_{*L*}*C*_{*T*}) and (*I*_{*L*}*L*_{*T*}), were compared. In summarization for both TRS and REC, conditions with and without the word concatenation score, (*I*_{*L*}*L*_{*T*}, *I*_{*L*}*L*_{*C*}_{*T*}) and (*I*_{*L*}*L*_{*L*}_{*C*}), were compared.

The summarization accuracies for manual summarization (SUB) is considered to be the upper limit of the automatic summarization accuracy. To ensure that our method is sound, we randomly generated summarization sentences (RDM) according to the summarization ratio and compared them with those by our proposed method.

These results show that our proposed automatic speech summarization technique is significantly more effective than RDM. By using the word concatenation score (*I*_{*L*}*L*_{*T*}, *I*_{*L*}*L*_{*C*}_{*T*}), meaning alteration is reduced compared with the case without using it (*I*_{*L*}, *I*_{*L*}*L*_{*C*}). The result obtained when using the word confidence score (*I*_{*L*}*L*_{*C*}_{*T*}) compared with those not using it (*I*_{*L*}*L*_{*T*}) shows that the summarization accuracy is improved by the confidence score. Table 2 shows the number of word errors and the number of sentences including word errors in the automatic summa-

(): number of sentences including recognition errors

ization results. It is shown that recognition errors are effectively reduced by the confidence score. In contrast with the confidence score which has been incorporated into the summarization score to exclude word errors by a recognizer, the linguistic score is effective to reduce out-of-context word extraction both from recognition errors and human disfluencies. In summarizing Japanese news speech, the confidence measure could improve the summarizing performance by excluding in-context word errors. In the English case, the confidence measure can not only exclude word errors but also help extracting clearly pronounced important words. Consequently the use of the confidence measure yields a larger increase in the summarization accuracy for English than Japanese.

6 Conclusions

Each utterance and a whole news article consisting of multiple utterances of English broadcast news speech were summarized by our automatic speech summarization method based on the following scores: word significance score, linguistic likelihood, word confidence measure and word concatenation probability. Experimental results show that our proposed method can effectively extract relatively important information and remove redundant and irrelevant information from English news speech in the similar way as Japanese.

Acknowledgment

The authors would like to thank Prof. Waibel, Mr. Markin and Mr. Hua (Carnegie Mellon University) for providing us with the results of English broadcast news speech recognition using JRtk. We also appreciate Dr. Yoshi Gotoh (Sheffield University) for an arrangement of generating the manual summarization.
